# SCRIPT-CONTROLLED ACL

## Level 5: Field-Based Rule

### *Define the Record-Level Condition*

**1.** Specify the field that controls access, such as Department.

**2.** Compare the record’s field value with the trusted department or access attribute of the logged-in user.

**3.** Grant access only when the values match and any required role check also passes.

**4.** Choose a secure default: deny access when the field is blank, the user attribute is unavailable, or the comparison cannot be completed.

**5.** Use exact, consistent values and consider whether read and write permissions need separate rules.
