SCRIPT-CONTROLLED ACL

Level 8: Verify and Document

Final Validation and Handover

1. Re-test the ACL after changes and verify that other application functions still work as intended.

2. Check that users cannot bypass the rule through alternate views, APIs, reports, or related interfaces, where applicable.

3. Document the objective, table and field, ACL configuration, script logic, test cases, outcomes, and known limitations.

4. Obtain the required review or approval before moving the configuration to a production environment.

5. Conclusion: The project demonstrates how a script-based ACL can restrict record access according to a trusted field value, supporting controlled access and least privilege.
